### Slide Title and Commentary

#### Objectives

SAY:

This presentation will address—

- The approach to diagnosing community-acquired pneumonia or CAP, chronic obstructive pulmonary disease or COPD exacerbation, and aspiration events
- The empiric treatment recommendations for CAP, COPD exacerbation, and aspiration pneumonia
- The opportunities for de-escalation of antibiotic therapy for CAP after additional clinical data are available
- The reasonable durations of antibiotic therapy for CAP after additional clinical data are available

#### The Four Moments of Antibiotic Decision Making

SAY:

As we discuss the diagnosis and treatment of CAP, we will continue to use the Four Moments of Antibiotic Decision Making framework.

As a reminder, Moment 1 asks: Does my patient have an infection that requires antibiotics?

Moment 2 consists of two questions and asks: Have I ordered appropriate cultures before starting antibiotics? What empiric therapy should I initiate?

Moment 3 consists of three questions and asks: A day or more has passed since initiating antibiotics. As I have more clinical and microbiologic data available can I stop antibiotics, can I narrow antibiotics, or can I change from intravenous to oral antibiotics?

And finally, Moment 4 asks: What duration of therapy is needed for my patient’s diagnosis?

### Slide Number and Slide

#### Slide 2

**Objectives**

1. Discuss the approach to diagnosing community-acquired pneumonia (CAP), chronic obstructive pulmonary disease (COPD) exacerbations, and aspiration events.
2. Discuss empiric treatment recommendations for CAP, COPD exacerbations, and aspiration pneumonia.
3. Discuss opportunities for de-escalation of antibiotic therapy for CAP after additional clinical data are available.
4. Discuss reasonable durations of antibiotic therapy for CAP after additional clinical data are available.

#### Slide 3

### Slide Title and Commentary

**The Four Moments of Antibiotic Decision-Making**

**SAY:**

The first moment of the Four Moments of Antibiotic Decision Making asks the question, “Does my patient have an infection that requires antibiotics?”

**Moment 1: Diagnosing CAP**

**SAY:**

A number of signs and symptoms commonly are observed with CAP. Cough and/or productive sputum are observed in over 90 percent of patients. Additionally, most patients have fevers, although this may be less common in the elderly.

About half of patients have chills or tachypnea and a third will complain of chest pain. Crackles are generally heard upon chest auscultation.
Moment 1: Diagnosing CAP

SAY:

Whenever a combination of these signs and symptoms are present, a chest x-ray should be obtained. The absence of an infiltrate on chest x-ray generally excludes the diagnosis of CAP. Similarly, the presence of an infiltrate on an x-ray obtained for an unrelated reason without the signs and symptoms of CAP is unlikely to be CAP.

If a patient has respiratory symptoms but does not have signs, symptoms, and imaging findings consistent with CAP, it is important to consider other causes of respiratory illness such as pulmonary embolism, asthma exacerbation, aspiration pneumonitis, or COPD exacerbations. These last two processes will be discussed later in this presentation.

The Four Moments of Antibiotic Decision Making

SAY:

During Moment 2, ask, “Have I ordered appropriate cultures before starting antibiotics? What empiric therapy should I initiate?”

Slide 6

**Moment 1: Diagnosing CAP**

- If common signs and symptoms are present, obtain chest x-ray
  - No infiltrates – indicates pneumonia not present
  - Presence of infiltrate without respiratory symptoms is unlikely to be CAP

Slide 7

**The Four Moments of Antibiotic Decision Making**

1. Does my patient have an infection that requires antibiotics?
2. Have I ordered appropriate cultures before starting antibiotics? What empiric therapy should I initiate?
Several diagnostic tests are available to assist with identifying the organism causing CAP. Blood cultures are recommended for patients who are moderately to severely ill or with chest imaging findings of a lung abscess or parapneumonic effusion. A sputum Gram stain and culture is recommended whenever a patient is able to produce sputum.

A respiratory viral panel is helpful as it could provide an alternative explanation for the patient’s clinical symptoms—particularly during respiratory virus season.

If a *Streptococcus pneumoniae* urinary antigen test is available at your institution, it can be helpful as a positive test can assist with the narrowing of therapy—depending on the agent initially started.

A *Legionella* urinary antigen should be considered, if available, for patients with moderate to severe symptoms, smokers, immunocompromised patients, or patients over 50 years of age. Of note, the Legionella urinary antigen only detects *L. pneumophila* serogroup 1 which is responsible for 70 to 80 percent of Legionella infections.

In severely ill or immunocompromised patients not responding to therapy and when the etiology of pneumonia is unknown, a bronchoscopy should be considered to assess for rare bacterial pathogens. These include *Legionella* and *Nocardia* and fungal pathogens such as *Pneumocystis jiroveci, Aspergillus*, and endemic fungi, and *Mycobacterium tuberculosis* and atypical *Mycobacteria*.
Moment 2: Empiric Therapy

SAY:

The Infectious Diseases Society of America and the American Thoracic Society Community Acquired-Pneumonia Guidelines for adults from 2007 recommend antibiotic regimens that cover both usual bacterial pathogens like *S. pneumoniae* and *H. influenzae* and atypical bacterial pathogens like *Legionella*.

There are several options for empiric therapy for CAP, but for most patients, current guidelines as of April 2019 suggest ampicillin-sulbactam and azithromycin or ceftriaxone and azithromycin as reasonable choices. Both ampicillin-sulbactam and ceftriaxone provide similar coverage for common bacterial causes of CAP. Azithromycin provides atypical coverage.

Ceftriaxone has more of an association with the development of *Clostridoides difficile* infection compared to ampicillin-sulbactam. But ceftriaxone is easier to administer as it is dosed less frequently and can be used in patients with non-severe penicillin allergies. Additionally, ceftriaxone provides broader coverage for *Enterobacteriaceae* such as *E. coli* and *Klebsiella* species, thus, some prefer it over ampicillin-sulbactam for patients admitted to the ICU.

For children with CAP in non-ICU settings, ampicillin or amoxicillin monotherapy are considered reasonable choices, if the child has not recently received amoxicillin. For adults with mild disease who are otherwise healthy, it is reasonable to consider ampicillin instead of ampicillin-sulbactam.

The addition of azithromycin to beta-lactam antibiotics has been shown to improve outcomes for adults with severe CAP. Although it can be considered for adult patients admitted to the general wards, data suggest that it may not improve outcomes for milder cases of CAP in non-ICU patients. The addition of doxycycline also provides coverage against atypical pathogens. Although no head-to-head trials compare outcomes of patients who received azithromycin or doxycycline as combination therapy for CAP, observational studies have suggested that macrolide-containing regimens are
<table>
<thead>
<tr>
<th>Slide Title and Commentary</th>

</tr>
</thead>
<tbody>
<tr>
<td>associated with better clinical outcomes for patients with severe CAP compared to other agents, possibly due to their immunomodulatory effects.</td>
<td></td>
</tr>
<tr>
<td>Respiratory quinolones such as levofloxacin and moxifloxacin are also options for CAP—particularly in patients with severe penicillin allergies. However, it is important to remember that quinolones are associated with some notable adverse events such as <em>C. difficile</em> infections, prolonged QTc intervals, tendinopathies, and altered mental status changes, especially in the elderly.</td>
<td></td>
</tr>
</tbody>
</table>
Moment 2: Empiric Therapy

In patients with recent respiratory viral infections presenting with bacterial pneumonia, consider coverage for *Staphylococcus aureus* including methicillin-resistant *S. aureus* or MRSA, in addition to standard antibiotics such as ceftriaxone. Coverage for MRSA such as vancomycin, linezolid, or trimethoprim-sulfamethoxazole should be considered in patients with cavitary lesions or if sputum Gram stain results reveal Gram-positive cocci in clusters.

Patients with bronchiectasis, those who received recent broad-spectrum antibiotic therapy, patients with a prolonged hospitalization, those admitted from a skilled nursing facility or nursing home in the past 3 months, or those who are immunocompromised may benefit from anti-pseudomonal coverage. Anti-pseudomonal agents such as cefepime or piperacillin-tazobactam should be considered for patients with these risk factors presenting with CAP, in addition to azithromycin.

During respiratory virus season, bacterial superinfections can be a concern. These are generally caused by *S. pneumoniae*, *S. agalactiae* (or Group A strep), and *S. aureus*. Generally patients have symptoms strongly suggestive of influenza followed by an improvement in signs and symptoms, with then a recurrence of fevers and respiratory findings. Chest x-rays should be obtained to evaluate for a new infiltrate. For patients admitted to the ICU with a concern for a bacterial superinfection, it is reasonable to start antibiotics with coverage against both *S. aureus* and *Streptococcus* species.

The Four Moments of Antibiotic Decision Making

SAY:

Moment 3 occurs after a day or more has passed. Ask: Can I stop antibiotics? Can I narrow therapy or change from IV to oral therapy?

Moment 3: Antibiotic Selection

SAY:

You can switch a patient to oral therapy as soon as clinical improvement is observed and the patient is able to tolerate oral medications.

There are several instances when you can narrow to amoxicillin, when broader therapy has been started initially.

If the sputum culture grows an amoxicillin or ampicillin-susceptible organism, if the streptococcal urinary antigen test is positive, or the proportion of S. pneumoniae isolates in your hospital that are penicillin resistant is low.

Azithromycin has a long half-life, so if it was initiated, 3 days of azithromycin is sufficient (unless you are treating Legionella).
### Moment 3: If NO Results Are Positive....

**SAY:**

If no cultures are positive, consider completing therapy with amoxicillin-clavulanate, oral second- or third-generation cephalosporins, or respiratory fluoroquinolones.

If a patient initially received ampicillin-sulbactam or IV cephalosporins, it is reasonable to convert to amoxicillin-clavulanate or an oral cephalosporin rather than switching to a respiratory fluoroquinolone which exposes the patient to additional risks from this class of antibiotics unnecessarily.

### The Four Moments of Antibiotic Decision Making

**SAY:**

The fourth moment of antibiotic decision making is asking the question, “What duration of antibiotic therapy is needed for my patient’s diagnosis?”

<table>

    - Oral second- or third-generation cephalosporins
    - Respiratory fluoroquinolones

| Slide 14               |

- The Four Moments of Antibiotic Decision Making

1. Does my patient have an infection that requires antibiotics?
2. Have I ordered appropriate cultures before starting antibiotics? What empiric therapy should I initiate?
3. A day or more has passed. Can I stop antibiotics? Can I narrow therapy or change from IV to oral therapy?
4. What duration of antibiotic therapy is needed for my patient’s diagnosis?
Numerous studies indicate that 5 days of antibiotic therapy is sufficient for most patients with CAP.

Consider prolonging therapy to at least 7 days if: The patient is immunocompromised, the patient has underlying structural lung disease (not including asthma), or the patient did not have an adequate clinical response to therapy within 72 hours.

If the patient has a nontraditional CAP pathogen such as Legionella, Pseudomonas aeruginosa, or S. aureus, longer durations of therapy are usually required, particularly if there is associated bacteremia.

A lingering cough and chest x-ray abnormalities may take several weeks to improve. There is no need to prolong antibiotic therapy or repeat imaging if the patient is otherwise showing improvement.

A number of RCTs have shown that antibiotic treatment for 5 days is as safe and effective as longer treatment courses. One RCT even demonstrated that therapy as short as 3 days is sufficient.

Data from bronchoscopy samples demonstrate 95 percent of patients with bacterial pneumonia eradicate pathogens after 3 days of therapy.

Additionally, two meta-analyses have shown short courses of antibiotic therapy are effective for the treatment of CAP.
### COPD Exacerbations

**SAY:**

Let’s move on to discuss exacerbations of chronic obstructive pulmonary disease or COPD.

### The Four Moments of Antibiotic Decision Making

**SAY:**

Remember, the first step is to ask yourself if your patient has an infection that requires antibiotics.

</tr>
</tbody>
</table>
The goal of antibiotic therapy for COPD exacerbations is to reduce the bacterial burden and not to necessarily eradicate bacteria.

Common bacteria associated with COPD exacerbations include *H. influenzae* and *S. pneumoniae*.

Sputum Gram stain and culture is not needed in many cases of COPD exacerbations, but can be considered for patients with extensive prior antibiotic exposure or a severe COPD exacerbation to understand what organisms the patient is colonized with.

Most patients can be treated empirically with a 3-day course of azithromycin.

If a patient is already taking azithromycin, consider doxycycline, amoxicillin/clavulanate, or cefuroxime for a 5-day course.

Avoid the use of fluoroquinolones unless prior or current cultures indicate infection with organisms resistant to standard therapy.

Finally, let’s discuss aspiration events and aspiration pneumonia.

</table>
### Slide Title and Commentary

**Observational Data**

SAY:

Is it safe not to treat aspiration events?

In one study evaluating 50 patients who were observed by physicians to have an aspiration event, initial symptoms included fever, tachypnea, diffuse rales, cyanosis, cough, wheezing, apnea, and shock. Chest x rays generally revealed diffuse or localized infiltrates which progressed over the next 24 hours.

In this cohort, 26 percent of patients progressed to bacterial pneumonia. Treatment with antibiotics at the time of the aspiration event did not appear to impact clinical outcomes.

**Antibiotics and Aspiration Pneumonitis**

SAY:

In an observational study of 200 patients with aspiration pneumonitis, 38 percent received prophylactic antibiotics soon after the aspiration event and 62 percent received supportive care only without antibiotic therapy.

The baseline characteristics were similar between the two groups. After adjustment for patient-level predictors of mortality, the in hospital mortality was similar between the groups at 25 percent and the need to transfer patients to the ICU was similar between the two groups at 5 percent and 6 percent.

---

### Slide Number and Slide

<td></td>
</tr>
</tbody>
</table>
Moment 3: Adjusting Therapy for Aspiration Events/Pneumonia

SAY:

For patients initially started on antibiotics after an aspiration event with a favorable clinical response: Rapid improvement in clinical status is anticipated within 48 hours of the aspiration event. If rapid improvement occurs, antibiotics can be discontinued.

For patients not initially started on antibiotics without improvement within 48 hours: Treat as community-acquired pneumonia if the event occurred within 72 hours of admission to a health care facility.

Treat as healthcare-associated pneumonia if the event occurred 72 hours or more after admission to a healthcare facility or if the patient has risk factors for resistant organisms such as coming from a nursing home.

Again, it is not necessary to add additional anaerobic coverage.

The Four Moments of Antibiotic Decision-Making

SAY:

The fourth moment of antibiotic decision making is asking the question, “What duration of antibiotic therapy is needed for my patient’s diagnosis?”
### Slide Title and Commentary

**Moment 4: Duration of Therapy for Aspiration Pneumonia**

**SAY:**

Duration should be determined based on clinical response and any relevant microbiology data. Most patients can receive 5 to 7 days of therapy.

### Take-Home Points

**SAY:**

To summarize some of the main take-home points from this presentation.

First, regarding CAP, before prescribing antibiotics for a patient with signs and symptoms suggestive of CAP, obtain a chest x ray and sputum Gram stain and culture. Oral antibiotic step-down therapy is recommended after clinical improvement is observed and most patients can be treated for a 5-day course of antibiotics.

Regarding COPD exacerbations, 3 days of azithromycin are generally sufficient. Fluoroquinolone use should be generally avoided, unless prior or current culture data for a specific patient suggests risk for or actual infection with organisms resistant to standard therapy.

And finally, regarding aspiration pneumonitis, for hemodynamically stable patients, antibiotics generally are not needed and supportive care is the mainstay of therapy. Prophylactic antibiotics have not been shown to be helpful in improving outcomes.

### Slide Number and Slide

**Slide 34**

**Moment 4: Duration of Therapy for Aspiration Pneumonia**

- Based on clinical response and organisms isolated
- Most patients: 5–7 days

**Slide 35**

**Take-Home Points**

- **CAP**
  - Before prescribing antibiotics for patients with signs and symptoms suggestive of CAP, obtain chest x ray and sputum Gram stain with culture.
  - Oral step-down therapy recommended after improvement observed.
  - Most patients can be treated for a 5-day course.

- **COPD Exacerbations**
  - 3 days of azithromycin are generally sufficient if antibiotics indicated.
  - Fluoroquinolones are not necessary for most patients.

- **Aspiration Pneumonitis**
  - For hemodynamically stable patients, antibiotics are not needed and supportive care is the mainstay of therapy.
  - Prophylactic antibiotics have not been shown to be helpful in improving outcomes.
