The *Pediatric Asthma Emergency Department Use Toolkit* is the product of collaboration among academic and research institutions, state and Federal agencies, and private sector stakeholders. Many individuals guided and contributed to the development of this toolkit.

This toolkit was developed by the IMPLementing MEasures NeTwork (IMPLEMENT) for Child Health team lead by Dr. Michael Cabana at the Albert Einstein College of Medicine in collaboration with colleagues at the University of Vermont Child Health Improvement Partnership (VCHIP) and the University of California, San Francisco, and funded by the Agency for Healthcare Research and Quality (AHRQ) and the Centers for Medicare & Medicaid Services (CMS) under the Pediatric Quality Measures Program (PQMP). The PQMP website is available at <https://www.ahrq.gov/pqmp/index.html>.

Introduction

This toolkit presents a children's health care quality measure from the AHRQ-CMS Pediatric Quality Measures Program (PQMP). The measure has been developed by PQMP Centers of Excellence (COE) grantee, Michael D. Cabana, M.D.

The goals of this toolkit are to:

1. Provide an overview of the Pediatric Asthma Emergency Department (ED) Use measure, and
2. Explain how to develop and implement quality measurement and improvement strategies in primary care settings to reduce asthma-related ED visits.

The Pediatric Asthma Emergency Department Use measure estimates the rate of ED visits for children ages 3 – 21 who are being managed for identifiable asthma, using specified definitions. Asthma is associated with increased hospitalizations and ED visits, a significant portion of which may be avoided with appropriate primary care asthma management.

This toolkit includes materials to support users in:

-
- Understanding the definition and use of the Pediatric Asthma Emergency Department Use measure,
 - Developing and implementing quality measurement and improvement strategies to reduce unnecessary pediatric asthma ED use, and
 - Improving adherence to National Heart, Lung, and Blood Institute (NHLBI) guidelines for managing pediatric asthma patients.
-

The intended audiences for this toolkit include states, health plans, health systems, improvement partners, and provider groups with a focus on primary care delivery.

This toolkit is organized into 4 sections:

1. Overview
2. About the Measure
3. Key Driver Diagrams
4. Quality Improvement Strategies

Overview

Asthma affects approximately 1 in 12 children in the United States (Akinbami, 2016). It is associated with increased hospitalizations and emergency department (ED) visits, as well as racial and ethnic disparities in outcomes (Cabana et al, 2006). A significant proportion of asthma hospitalizations can be avoided with appropriate primary care asthma management (Homer, 1996). There are many factors that can lead to a child with asthma receiving care in the ED: poor asthma control, severity of symptoms, decreased access to care, and ability to enact emergency care, among many others. There are also numerous factors and settings that impact the asthma ED measure, including schools, ED, acute care, access to specialist, and community, many of which must be considered in trying to reduce inappropriate ED use for pediatric asthma. Primary care quality improvement (QI) collaboratives have been shown to be effective in improving asthma care processes and decreasing asthma-related emergency department visits.

The goal of this toolkit is to provide an overview of the measure: Pediatric Asthma Emergency Department Use and explain how to develop and implement quality measurement and improvement strategies in primary care settings to reduce asthma-related ED visits. The measurement specifications and QI strategies can be used by states, health plans, health systems, improvement partners, and provider groups to successfully improve asthma care.

MEASURE DESCRIPTION

The Pediatric Asthma Emergency Department Use measure estimates the rate of ED visits for children ages 3 – 21 who are being managed for identifiable asthma, using specified definitions. The measure is reported as number of visits per 100 child-years.

MEASURE STEWARD

The measure stewards are the University of California San Francisco and the Children's Hospital at Montefiore.

END USERS

Potential end users of the measure include local and state health departments, health plans, health systems, accountable care organizations, improvement partners, provider groups, and primary care practices/clinics.

This toolkit provides information about the measure, including specifications and reporting prepared by the measure stewards. The toolkit also describes QI activities that can be achieved by working with primary care learning collaboratives to improve adherence to National Heart, Lung, and Blood Institute (NHLBI) guidelines and reduce unnecessary pediatric asthma ED use. The QI materials and resources provided were developed by IMPLEMENT for Child Health initiative, based in San Francisco, California, and the Vermont Child Health Improvement Program (VCHIP).

About the Measure

The Pediatric Asthma Emergency Department Use measure estimates the rate of emergency department (ED) visits for children who are being managed for identifiable asthma.

Asthma is associated with increased hospitalizations and ED visits, as well as racial and ethnic disparities in outcomes (Cabana, 2007). There are many factors that can lead to a child with asthma receiving care in the ED: poor asthma control, severity of symptoms, decreased access to care, and ability to enact emergency care, among many others. There are also numerous factors and settings that impact the asthma ED measure, including schools, ED, acute care, access to specialist, and community.

MEASURE SPECIFICATIONS AND REPORTING

This measure estimates the rate of ED visits for children ages 3 – 21 who are being managed for identifiable asthma, using specified definitions. The measure is reported in visits per 100 child-years.

This measure requires administrative data and is calculated as follows:

of asthma-related ED visits and hospitalizations
100 child-years for children with identifiable asthma

Detailed measure specifications and other materials needed to implement the measure using administrative data are available below:

-
- Measure Technical Specifications: This document summarizes the measure technical specifications, providing a high-level description of how the measure is calculated.
 - SAS Code: This document provides SAS code to produce the member-month datafiles to calculate the measure as described in the measure.
 - ICD/CPT Codes: This Excel file contains the codes used to define elements of the measure specifications. Both ICD-9 and ICD-10 codes are included so that data can be analyzed before and after the switch to ICD-10. The codes are embedded into the SAS code, but they are provided here separately for ease of review.
 - Input File Specifications: This Excel file provides definitions and names for input variables needed for the files to be processed using the provided SAS code. This allows measure implementers to choose and rename the input variables from the administrative claims they are using in calculating the measure.
 - Flow Diagram for Measure Coding: This document provides a visual map and representation of the data processing steps needed to take raw administrative claims datafiles and create the

measurement files as described in the measure specifications. The diagrams visually represent what the posted SAS code does. In other words, the SAS code implements the processing steps, and the flow diagrams are aids to understanding the SAS code.

These items can be downloaded from the AHRQ website at
<https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/qi-strategies.html>.

Key Driver Diagram

Successful quality improvement (QI) work, including the effective use of Key Driver Diagrams (KDDs), requires sound QI science methodology, appropriate resources, and ready access to reliable data. Key success factors necessary to achieve results are described in the QI strategies section of this toolkit.

KDDs can be used to help organize system-thinking around a Specific, Measurable, Achievable, Realistic and Timely (SMART) Aim to guide QI strategies. Development of KDDs is an iterative process to explore systems issues and possible interventions to impact the SMART Aim. For the KDDs in this toolkit, the SMART Aim was to reduce the number of ED visits for children with persistent asthma and impact the pediatric asthma ED measure.

This toolkit contains three KDDs: an overall KDD that summarizes key drivers that impact the measure, as well as two initiative-specific KDDs that demonstrate the specific drivers involved in the two primary care QI initiatives described in this toolkit.

The PQMP asthma measure is an outcome measure impacted by three distinct phases of care, which are highlighted in the two KDDs describing primary care initiatives: (I) Prevention, (II) Acute Episode Management, and (III) ED Care. The KDDs are available below:

-
- **PQMP National Asthma Quality Metric Key Driver Diagram:** This “overall” KDD includes examples of strategies that can be adapted and tailored for use by organizations. The interventions focus on various aspects of improving asthma care in primary care settings to support systematic and comprehensive asthma care delivery and monitoring. The KDD is available at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.
 - **PQMP National Asthma Quality Metric Key Driver Diagram (Vermont):** This KDD demonstrates the subset of drivers used in the University of Vermont QI initiative. It was designed for practices with prior QI experience and already adhering to National Heart, Lung, and Blood Institute (NHLBI) guidelines. This initiative focused on *improving clinical asthma management measures through improvement of office systems to support asthma care* (e.g., management and follow-up of an acute episode, team-based asthma education). These strategies were aimed primarily at Acute Episode Management processes of care. As an additional resource, the detailed strategies employed in the Vermont Learning Collaborative are summarized at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.
 - **PQMP National Asthma Quality Metric Key Driver Diagram (San Francisco):** This KDD demonstrates the subset of drivers used in the University of California San Francisco QI initiative. It was designed for a group of primary care practices with limited or no prior experience in QI and the strategies implemented focused on *ensuring provider adherence to NHLBI guidelines for managing pediatric asthma patients* (e.g., asthma control assessment, completion

of asthma action plans, and severity documentation). These strategies were aimed primarily at Prevention processes of care. The KDD is available at

<https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>

Although each initiative involved a different set of QI strategies, the global aim of each was to test and implement national performance measures that accurately assessed components of quality care for children with asthma, with a focus on reducing the number of ED visits/100 child-years for children managed for persistent asthma.

Quality Improvement Strategies

This section of the toolkit describes key factors that promote success in quality improvement (QI) initiatives and provides supportive resources. It describes the settings and the multiple factors that impact the asthma ED measure. You can navigate directly to [Approaches to Quality Improvement in Asthma Care section](#).

The toolkit also provides more detailed guidance on implementing primary care learning collaboratives based on the experiences from two initiatives that aimed at reducing ED use among pediatric asthma patients and examining the asthma ED use measure. Navigate directly to [Quality Improvement with a Focus on Primary Care Delivery section](#).

Within that section, the toolkit presents a “phased” approach to QI so that users can tailor their goals and strategies based on their prior experience in implementing QI activities. Practices with limited or no prior QI experience are encouraged to start with Phase 1, initiating a learning collaborative to assess and improve NHLBI guideline adherence in primary care. For practices with prior experience implementing NHLBI guidelines and using QI strategies, this toolkit describes a “deep dive” approach to improve existing processes, designated Phase 2.

KEY SUCCESS FACTORS FOR QUALITY IMPROVEMENT

The PQMP measure, Pediatric Asthma Emergency Department (ED) Use, is an outcome measure based on administrative data. In that context, the toolkit user entity (state agency, health plan, healthcare organization, improvement partnership, provider group) will need to partner with practices and quality improvement (QI) coaches to evaluate systems and develop process measures to guide improvement efforts that will impact the measure. Process measures can be developed from clinical guidelines such as the [National Heart Lung and Blood Institute \(NHLBI\) Guidelines for the Diagnosis and Management of Asthma](#).

It is important to recognize that most process measures will be contained in a practice’s electronic health record (EHR) or a data source separate from claims data. Additionally, effective process measures should be evaluated longitudinally to assess performance over time and allow for identification of variation, either intended or unintended.

Successful improvement requires sound QI science methodology, appropriate resources and ready access to reliable data. Without these components (appropriate training, infrastructure and data access), application of QI may lead to unintended consequences, such as provider frustration or QI ‘fatigue’.

The table below summarizes the strategies and complementary toolkit resources available to support implementing quality measurement and improvement strategies in primary care settings to reduce asthma-related ED visits from the perspective of a health plan.

Summary of Strategies and Complementary Toolkit Resources

Goal	Resources Required	Resources in Toolkit	Health Plan Contributions
Strategy: Improvement Science Approach			
Appreciate the system of care for children with asthma	Understand the population and the system resources in your care delivery area	Refer to PQMP National Asthma Quality Metric Key Driver Diagram.	Foster partnerships and determine strategic alignment(s)
Strategy: Collaborative			
Partner with practices in Health Plan network	Practice network		Engage practices in collaborative
Engage practice leadership	Practice champion		Financial alignment for clinical champion(s)
Develop improvement science expertise	QI Coaching	Refer to QI Knowledge Survey.	Offer financial support for QI infrastructure
Determine baseline performance on NHLBI measures	Process measures from EHR	Refer to Baseline Chart Review Tool.	Support practices to engage EHR vendor/ practice support to obtain data
Assess periodic performance/ improvement over time		Refer to measures monitored by the SF Collaborative.	Develop practice-based incentives for improvement
Understand variation in performance and guide improvement efforts	Practice level strategies	Refer to OSI tool.	
Strategy: Continuous Improvement			
Systems learning	Practice data of children who went to ED	Refer to Practice Participation Flow Chart.	Health plan provides practice reports
Systems learning	Practice-based clinician(s)/chart auditor	Refer to Practice Data Collection Form.	

Resources in the Toolkit are available on the AHRQ website at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/qi-strategies.html>

APPROACHES TO QUALITY IMPROVEMENT IN ASTHMA CARE

This section introduces the range of approaches aimed at decreasing pediatric asthma ED visits and important factors for determining which approach may be most appropriate to take. Specific guidance on implementing a primary care learning collaborative is provided in the next few sections.

There are numerous factors and settings that impact the asthma ED measure (e.g., schools, ED, acute care, access to specialists, community, etc.), and these must be considered in trying to reduce inappropriate ED use for pediatric asthma. Many factors can lead to a child with asthma receiving care in the ED such as poor asthma control, severity of symptoms, decreased access to care, and ability to enact emergency care (such as use of a rescue inhaler) among many others. When thinking of these factors and where they occur, they generally can be attributed to the patient's home and school environment, medical home, the ED, or a combination (Allen, 2019). Interventions engaging the ED should be considered if there is a high rate of patients with multiple visits to the ED. In this scenario, it is important to evaluate access to care, environmental factors, ED care, and the connection between the ED and the medical home.

Though there are several evidence-based QI strategies to decrease ED visits for pediatric asthma, there is insufficient evidence to recommend a single approach or set of interventions over another because there are many factors that influence what will be the most effective approach for a care system. Some systems with a high degree of integration and QI capacity have chosen multiple interventions to reduce ED visits (Allen, 2019). However, most care systems will likely be best served by selecting a single approach after evaluating their outcome and process measures while identifying the key drivers of performance. Assembling an interprofessional team to understand key stakeholder priorities and readiness coupled with a thorough and systematic approach to QI are essential to achieving success.

There are three general QI approaches to decrease pediatric ED visits for asthma that have a strong evidence base: Primary Care, Provider Continuing Medical Education, and Parental and School-Based. Following an overview of each approach, there is a brief introduction to the primary care learning collaboratives, one of which was formed as part of the PQMP grant, that examine the usability of the asthma ED measure. The work of these initiatives forms the basis of this toolkit, and is described in more detail in the next few sections, which can be accessed at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/qi-strategies.html>.

PRIMARY CARE-FOCUSED APPROACH

Most interventions that have been successful in improving asthma ED outcomes through provider-based activities have included intensive educational approaches or methods to develop improved systems of care within the primary care office setting. Harder et al. examined the effects of a one-year QI collaborative for primary care clinicians that focused on office systems strategies (e.g., asthma assessment, control and management, and patient education). Although there was no immediate effect noted, compared to control practices, the participating practices noted a substantial decrease of

nearly 40 percent in asthma-related ED visit rates more than a year after the end of the collaborative (Harder, 2020). The development of a systematic primary care approach to asthma care can also improve asthma health care utilization. In a pragmatic, cluster randomized controlled trial, Yawn et al. demonstrated that the use of Asthma APGAR (Activities, Persistent, triGGers, Asthma medications, Response to therapy) tools improves rates of asthma control and reduces asthma-related ED and urgent care visits (Yawn, 2018).

PROVIDER CONTINUING MEDICAL EDUCATION APPROACH

Although traditional continuing medical education (CME) interventions have not been consistently effective in changing provider behavior; intensive, small group CME may make a difference. In a large national randomized control trial, a physician asthma education program, led by local opinion leaders, that focused on improving physician counseling skills and medication selection, along with resources for education, coding, and billing was effective in decreasing asthma ED use (Cabana, 2006). Timely feedback about patient symptoms may also help improve clinician management of asthma. For example, provider feedback about patient symptoms was shown to improve and change provider behavior and increase the frequency of asthma visits to adjust medications, but also reduce ED visits for asthma (Kattan, 2006).

PARENTAL AND SCHOOL-BASED EDUCATION APPROACH

Parental understanding of asthma is an important component in helping children self-manage asthma. There have been mixed results in parent educational interventions (Nelson et al., 2011). Intensive parent education has also been shown to impact management and ED asthma visits (Chong, 2019), as well as asthma education and case management (Greineder, 1999). The use of home-based educational and environmental intervention delivered by lay health educators would improve asthma symptom control in inner-city children with asthma and has been shown to decrease ED visits (Bryant-Stephens, 2009). Finally, school-based interventions, “to help children improve management of their asthma by increasing knowledge, enhancing skills, or changing behaviour” have been associated with slightly decreased ED asthma visits (Harris, 2019).

PQMP TOOLKIT APPROACH: PRIMARY CARE COLLABORATIVES

The PQMP asthma measure has the potential to improve asthma care, reduce ED utilization, and promote collaboration between health plans and primary care practices. Successful utilization of the measure will necessitate interpreting data from multiple sources and business entities. Because of this, there will be practical, ethical, and legal limitations relative to sharing data and how improvement efforts are implemented. While all of the approaches described above have merit, the PQMP grantees charged with testing how to use the pediatric ED use measure chose to focus on primary care, the intervention area with the most evidence of success. This toolkit outlines primary care-focused interventions using an intensive educational approach and methods to develop improved systems of care.

The IMPLementing MEasures NeTwork (IMPLEMENT) for Child Health initiative is the overall program that tested out the usability of the PQMP asthma ED measure by conducting QI initiatives in

San Francisco, California (SF Collaborative) and in Burlington, Vermont (VT Collaborative). Both QI initiatives aimed to improve pediatric asthma care delivered in a primary care setting while examining the usability of the asthma measure. The strategies described in this toolkit reflect the learnings from the two QI initiatives. In the SF Collaborative, primary care practices participated in a 12-month learning collaborative. In the VT Collaborative, practices had participated in an earlier Vermont statewide asthma learning collaborative. Therefore, a more targeted approach was undertaken – performing a “deep dive” to examine factors that contributed to high ED rates. Select for more information on the earlier [Child Health Advances Measured in Practice \(CHAMP\) Learning Collaborative](#). Staff and faculty from the University of Vermont’s Vermont Child Health Improvement Program’s (VCHIP) provided the QI expertise for both initiatives.

Primary care learning collaboratives can be adapted based on the participants’ level of prior experience with QI activities. The support of practice leadership, clinicians, and operational staff are essential in successfully operating a primary care collaborative. Furthermore, partnerships with the clinicians from the practice, as well as commitment to looking into the complexity of the problems and processes involved, using QI methodologies, and communicating with and including members of the practice throughout the learning process are critical factors in any QI project’s success.

The next section of the toolkit describes a phased approach to implementing a learning collaborative in primary care aimed at reducing ED use among pediatric asthma patients based upon the experiences from the two initiatives with input from QI experts.

QUALITY IMPROVEMENT WITH A FOCUS ON PRIMARY CARE DELIVERY

Both the SF and VT Collaboratives used practice-level data to determine how and where to intervene using QI strategies based on the Institute for Health Improvement’s (IHI) [Learning Collaborative model](#). Although the initiatives involved different strategies depending on the prior experience of the primary care practices with improving asthma care, all of the strategies were intended to contribute to a reduction in inappropriate ED use.

These collaborative initiatives can be sponsored by a managed care plan, health system large provider group, or Improvement Partnership as described in Shaw 2013, and are designed to support primary care practices focusing on ensuring provider adherence to NHLBI guidelines for managing pediatric asthma patients and implementing system-level changes to improve asthma care.

Practices are encouraged to assure they have a QI infrastructure that will promote rapid and sustainable improvement. Key components of a high-functioning QI team include clinical champions, leadership support, a quality coach and the ability to generate actionable data – including reporting. Additionally, a practice’s ability to be receptive to change and modify practices is essential to a learning organization. There are several tools that can help reinforce components of the QI team to promote success at the practice level, including the article entitled Modeling for Understanding Success in Quality (MUSIQ) (Kaplan, 2012).

WHERE TO START

Primary care practices and the organizations supporting them with limited or no prior QI experience are encouraged to take the approach described below as Phase 1.

- The SF Collaborative provides an example of this approach. Adherence to the NHLBI guidelines, as determined through process measures, is a first step in ensuring that a primary care practice can best serve its pediatric asthma patients.
-

Primary care practices already experienced in implementing NHLBI guidelines and using QI strategies can take the approach described below as Phase 2.

- The VT Collaborative provides an example of working with primary care practices already adhering to NHLBI guidelines with prior experience in an asthma QI collaborative. These practices were ready to take a “deep dive” into their existing processes.
-

PHASE 1 – LEARNING COLLABORATIVE FOR NHLBI GUIDELINE ADHERENCE

For primary care practices with limited or no prior QI activity in improving asthma care, the learning collaborative should focus on ensuring adherence to NHLBI guidelines for pediatric asthma care.

The SF Collaborative focused on establishing consistent use of NHLBI guidelines among providers and ensuring key process measures were completed as part of every patient’s asthma care. Strategies included increasing asthma control assessment, developing an asthma action plan, performing spirometry and improving asthma education for patients and families. The learning collaborative follows the standard format as described by the IHI in the white paper titled, “The Breakthrough Series: IHI’s Collaborative Model for Achieving Breakthrough Improvement” (IHI, 2003).

Typical learning collaboratives include at least one face-to-face meeting, followed by monthly conference calls and are led by a group with experience in quality improvement. At the initial meeting, participants are educated on the Plan, Do, Study, Act (PDSA) cycles, and data is shared based on the metrics and measures chosen. The SF Collaborative was assisted by the QI faculty and staff from the VCHIP and the materials from the CHAMP Learning Collaborative were adapted for use in SF. For a more detailed description of the approach that was adapted, refer to the article entitled “A primary care learning collaborative to improve office systems and clinical management of pediatric asthma” (Weinberger, 2019) which includes the tools used during the collaborative. Primary care practices participating in the CHAMP Learning Collaborative improved clinical asthma management measures through improvement of office systems to support asthma care. The initiative included evaluating seven months of medical record review data for improvements on eight clinical asthma management measures and the use of pre and post office systems inventory self-assessments.

In the SF Collaborative, practices followed a similar process to those used in the CHAMP Learning Collaborative in Vermont, attending a one-day face-to-face learning session and monthly collaborative conference calls. A sample agenda is available. Prior to the learning session, practice participants completed the QI knowledge survey. It is important to assess the attendees' knowledge and experience with QI and adapting the collaborative to meet the learners' needs. In the VT Collaborative, practices were members of the CHAMP statewide QI network, thus the level of attendee knowledge was already known. However, in the SF Collaborative a survey was designed to assess the knowledge base of potential collaborative attendees related to QI. Conducting such an assessment in advance of holding a collaborative and developing the final agenda and materials using this knowledge will help ensure the collaborative work starts at the appropriate level to promote progress in improving asthma care.

Baseline data is typically collected by the practice (through chart review) to establish practice performance relative to the agreed upon collaborative measures. Asthma measures and corresponding goals were decided by the IMPLEMENT team prior to the start of the learning collaborative. Descriptions of the measures monitored by the SF Collaborative and the document used for sample baseline chart review can be accessed at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.

At the learning session, topics included basic principles of QI, education including NHLBI guidelines for asthma care, and practice-level baseline data presentation. Ample time was allowed for practice-based teams to develop their first PDSA cycle of improvement. Following the learning session, practices submitted monthly data and participated in monthly collaborative calls where project-level data was presented as progress towards collaborative goals.

A key tool used in the CHAMP Learning Collaborative and adapted for use in the SF Collaborative is the Office Systems Inventory (OSI), a document that categorizes and lists strategies to help improve asthma care. View the tool at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>. The OSI lists the strategies that healthcare professionals and primary care practices can use to improve their office systems to promote optimal asthma treatment. Examples of specific strategies included on the OSI are assessing the child's asthma control at every visit using a validated tool, using an asthma action plan as a communication tool with the family, and integrating education into all points of care by including members of all health care disciplines.

The purpose of the OSI strategies document is to help practices identify areas where there are gaps in their systems or processes that they can focus on in their improvement efforts. Teams can go through this document together at the start of an improvement effort and document if each of the strategies is: not done, done inconsistently, done consistently, or consistently done based on best practice. At the completion of an improvement effort, the practice team can complete the strategies self-assessment again to identify systems changes and improvements made.

To further support using the learning collaborative approach as the first phase in utilizing the PQMP asthma measure, VCHIP examined if participation in the CHAMP Learning Collaborative was associated with a decrease in asthma-related ED utilization over time compared to controls. The findings described in “Statewide Asthma Learning Collaborative Participation and Asthma-related Emergency Department Use” reports that participation in the CHAMP Learning Collaborative was associated with a substantial decrease in asthma-related ED visits, compared to controls, more than a year after the end of the collaborative (Harder, 2020).

PHASE 2 – DEEP DIVE TO UNDERSTAND PEDIATRIC ED USE

When primary care practices have successfully engaged in asthma QI activities, a health plan, accountable care organization (ACO), or health system may choose work with practices to more closely examine or take a “deep dive” into the reasons patients are using the ED for pediatric asthma care. This phase involves a retrospective review process in primary care to understand the ‘population’ of each primary care practice’s patients who go to the ED. This deep dive process requires an organizational commitment and investment of resources including assisting with the identification of practice patients with ED visits, conducting the retrospective chart reviews, and supporting the application of QI methods to identify areas for improvement and coaching in improvement efforts.

The following section provides examples of tools that an organization can use in implementing Phase 2.

Taking a deep dive to understand the reasons patients are using the ED for pediatric asthma care involves three main steps:

1. Identify practice patients with ED visits.
2. Use Practice Asthma Data Collection Tool to retrospectively examine asthmatics accessing the ED.
3. Implement QI activities.

As an additional resource, the detailed strategies employed in the Vermont Learning Collaborative are summarized at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.

DEEP DIVE – STEP 1. IDENTIFY PRACTICE PATIENTS WITH ED VISITS

Step 1 is designed to compile a complete and accurate identification of patients with asthma in each primary care practice and identify who has had an asthma-related ED visit in the last six to 12 months. While the list can be generated by a practice, a health plan, or a health care system (e.g., ACO), there are benefits and limitations of each scenario to consider. A practice-defined list provides the most comprehensive capture of patients. Health plan or ACO data is limited to the patients they insure or are accountable for, and thus may limit the generalizability of the chart review findings.

Once the list of patients with asthma-related ED visits is compiled, the QI team should review the associated ED utilization data.

Although seemingly simple, a practice without an asthma registry may find it challenging to identify all their patients with asthma and then to determine if they have had an ED visit. Working with a health plan, ACO, or other organization with access to billing data for a specific population to provide the practice with a list of patients with ED visits could be beneficial but would be limited to the patients they insure.

To view a flow chart describing the process an entity can take to identify and monitor the pediatric asthma care provided to its members, go to <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>. Health plans are able to use the ICD-10 codes to define children with asthma and include them in the analysis. The codes also are available to download as an Excel file at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>

An example of a joint effort between a payer and a practice with an asthma registry to identify patients with an ED visit is described below:

A QI team, comprised of payer and practice staff, reviews data for children covered by the health plan. Additionally, the practice reviews the parameters of their asthma registry with the payer, including ICD-10 codes, medication groupers, and demographic data. While this measure is designed to be interpreted by the payer, interventions to improve process measures at the practice level must be agnostic of insurance coverage due to the potential for inequity. Because of this, practices should not be expected to provide process measures based on health plan coverage.

DEEP DIVE – STEP 2. USE PRACTICE ASTHMA DATA COLLECTION TOOL TO RETROSPECTIVELY EXAMINE ASTHMATICS ACCESSING THE ED

Once asthmatics with one or more ED visit are identified, a retrospective chart review is conducted. The chart review involves a 'look back' from the date of the most recent ED visit and should include a range of ages from 3-21 years. In the VT Collaborative, 25 charts were reviewed, although that total number can vary depending upon the size of the practice and the number of asthmatics with ED visits. In smaller practices, this may cover close to a one-year period, while in larger practices, 25 charts may cover a shorter period. There is no prescribed number of charts, but the process should include sufficient numbers to capture gaps in care that could be identified as areas for improvement. Refer to the Practice Asthma Data Collection Form available at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.

The chart review questions were developed and refined multiple times with broad input from clinicians and QI experts. Research Electronic Data Capture (REDCap), an online secure data collection tool that meets HIPAA compliance standards, housed the survey for the VT Collaborative. Sites wishing to import the Vermont survey directly into their own version of REDCap may download the REDCap survey tool Excel file at <https://www.ahrq.gov/pqmp/implementation-qi/toolkit/asthma/index.html>.

Practices may opt to create a different mechanism for data capture and can use the questions in the file to inform their own survey development. The survey is broken into 10 areas, which capture the key themes of the NHLBI Expert Panel Report (EPR-3) guidelines: 1) patient demographics, 2) ED utilization, 3) prior healthcare utilization, 4) asthma severity and control, 5) medications, 6) spirometry, 7) asthma education and self-management, 8) tobacco use assessment, 9) allergies, and 10) other factors.

Once collected, the data are analyzed, and descriptive statistics (absolute counts and relative percentages) are produced. REDCap has the functionality for data analysis and a person familiar with REDCap should assist with this step.

The chart review data collected for the VT Collaborative included data from multiple insurers and analysis was conducted by an academic institution. Confidentiality was maintained and data was not shared beyond the practice. This approach can be replicated by health plans, ACOs, or health systems to monitor delivery of pediatric asthma care. They can work with clinicians and healthcare teams to collect and interpret the data, identify problems, and determine courses of action to drive improvement in patients' health. The following example illustrates how one group of healthcare teams used this approach.

An example from the VT Collaborative using the chart audit tool is described below:

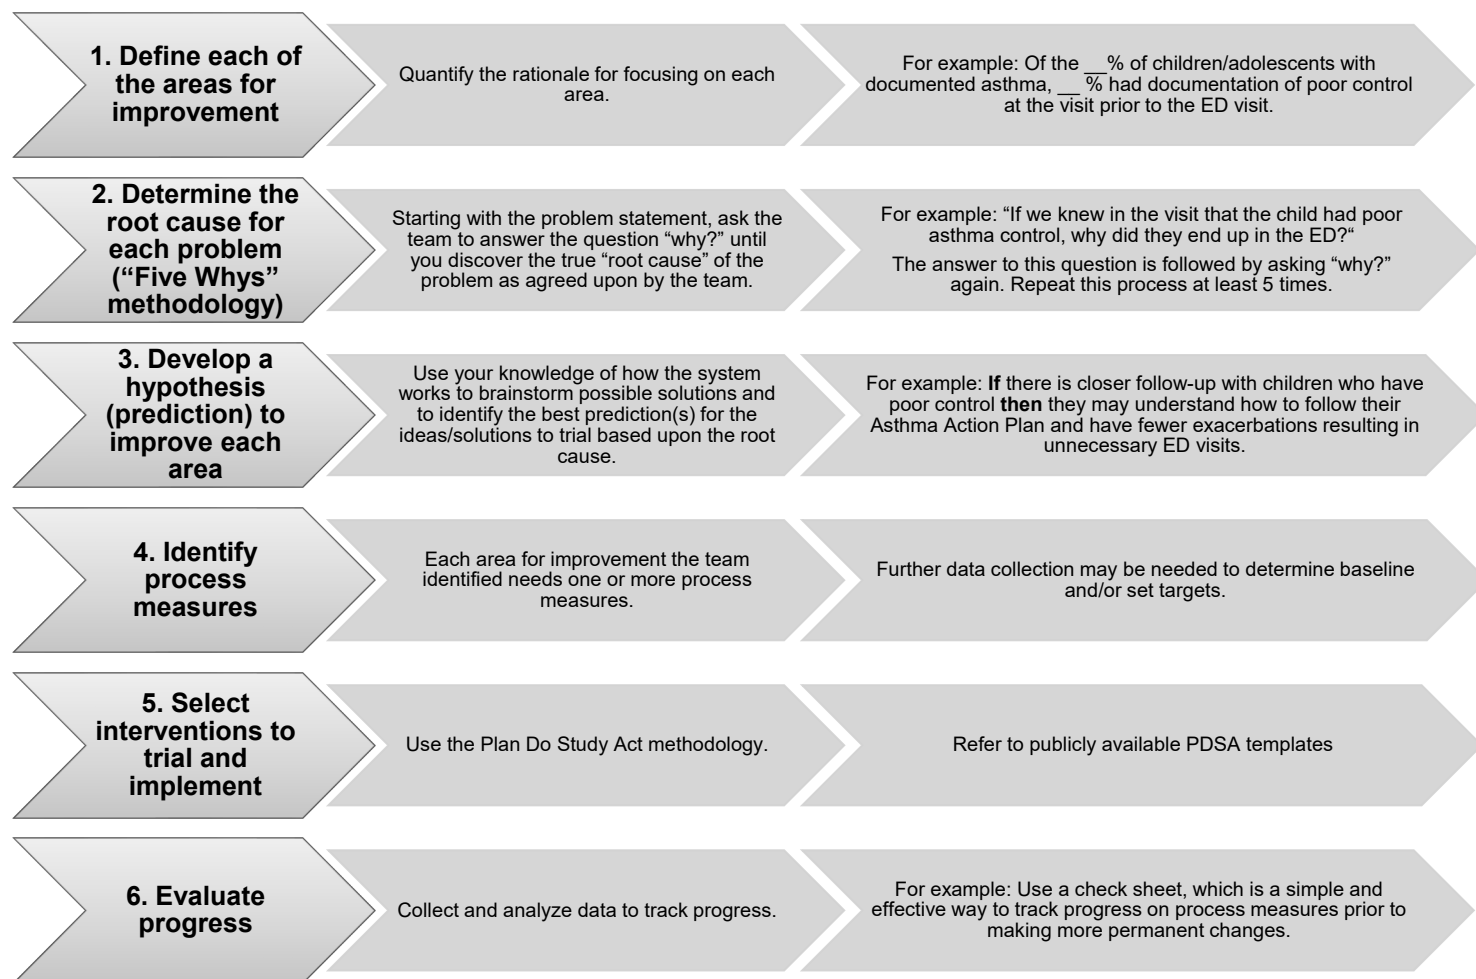

The QI team recognized that NHLBI guideline adherence alone would not address the root causes of why some children with asthma end up in the ED. To mitigate unnecessary ED visits, a system to collect information retrospectively from medical charts was developed, including information not typically captured in patient charts (e.g., information on social needs). Preferably the chart review is conducted by someone in the practice with a clinical background (MD, PA, NP, RN) because they are familiar with the practice and can participate in the review of the post-chart review data. In Vermont, two nurse practitioners conducted the chart review.

DEEP DIVE – STEP 3. REVIEW OF KEY PRACTICE-WIDE PROCESS MEASURE PERFORMANCE AND INITIATION OF QI ACTIVITY

As noted, this deep dive process requires a skilled QI coach to assist practices with analysis of the chart review data and to help determine areas for improvement. Step 3 involves a highly iterative process and requires significant clinician engagement and training in QI. The QI coach should be familiar with QI methods and strategies and will choose the approach most appropriate for the practice staff and clinician(s) knowledge and skills and the available resources devoted to the improvement process.

The following flow diagram depicts the typical steps required in ongoing QI work.

Flow Diagram of the Steps in the QI Problem-Solving Process

The iterative process used to achieve success in the VT Collaborative is described below as an illustrative example of Step 3:

Targeted coaching on use of data. *The primary care clinical team received targeted coaching to increase the team’s fundamental knowledge, aptitude for developing impactful interventions, and practical skills. The QI coaches conducted learning sessions about interpreting the data and understanding the implications of strategies to improve office systems (e.g., workflows, resources, team approaches). During these sessions, clinicians developed theories and planned interventions. Between meetings, clinicians conducted observations of office systems. These observations were discussed at the quality team meetings and the team engaged in fruitful discussions about the nature of variation in any system. Differences in practice patterns between office personnel were identified as central to either wasteful or highly effective workflows. The improvement team integrated hypotheses, data, and office*

systems into meaningful process measures that they anticipated would lead to eventual improvement in the outcome measure (e.g., Increase percent of follow-up calls to provide asthma education and information to patients/families when the patient had documentation of poor asthma control at the visit).

Identifying opportunities for improvement. The team then sought to identify the most significant problems or improvement opportunities, to understand why they were occurring, and to address the opportunities for improvement. Using a flowchart to understand the processes in which the problems occur can be helpful, especially when the team includes members who have differing levels of knowledge about and experience with practice processes. Based upon their review and discussion of the results of the chart audit, the team identified four specific areas for improvement that, if addressed, could help to decrease potentially avoidable ED visits. The team assessed each of the four areas for improvement individually to gain a deeper understanding and to identify and understand the “root cause” of the factors that could lead to these ED visits.

Conducting a root cause analysis. The QI coach facilitated the root cause analysis and helped the team to further explore each of the four areas identified for improvement. The team was then able to identify specific process measures and select interventions to trial and implement in the practice setting. The root cause analysis was used working with the full healthcare team’s involvement so they could gain optimal understanding of “how” the system works using the “Five Whys” Root Cause Analysis process. The IHI describes this process and provides a PDF guide at the following webpage: <http://www.ihl.org/resources/Pages/Tools/5-Whys-Finding-the-Root-Cause.aspx>.
